Gärdenfors (2000):

- meanings are arranged in **conceptual spaces**
- conceptual space has geometrical structure
- dimensions are founded in perception/cognition

Gärdenfors (2000):

- meanings are arranged in **conceptual spaces**
- conceptual space has geometrical structure
- dimensions are founded in perception/cognition

## Convexity

A subset  $C$  of a conceptual space is said to be *convex* if, for all points  $x$  and  $y$  in  $C$ , all points between  $x$  and  $y$  are also in  $C$ .

Gärdenfors (2000):

- meanings are arranged in **conceptual spaces**
- conceptual space has geometrical structure
- dimensions are founded in perception/cognition

## Convexity

A subset  $C$  of a conceptual space is said to be *convex* if, for all points  $x$  and  $y$  in  $C$ , all points between  $x$  and  $y$  are also in  $C$ .

## Criterion P

A *natural property* is a convex region of a domain in a conceptual space.

- spatial dimensions: *above, below, in front of, behind, left, right, over, under, between ...*
- temporal dimension: *early, late, now, in 2005, after, ...*
- sensual dimensions: *loud, faint, salty, light, dark, ...*
- abstract dimensions: *cheap, expensive, important, ...*

- two players:
  - **S**ender
  - **R**eceiver
- infinite set of **M**eanings, arranged in a finite metrical space  
*distance is measured by function  $d : M^2 \mapsto R$*
- finite set of **F**orms
- sequential game:
  - 1 nature picks out  $m \in M$  according to some probability distribution  $p$  and reveals  $m$  to  $S$
  - 2  $S$  maps  $m$  to a form  $f$  and reveals  $f$  to  $R$
  - 3  $R$  maps  $f$  to a meaning  $m'$

- **Goal:**
  - optimal communication
  - both want to minimize the distance between  $m$  and  $m'$
- **Strategies:**
  - speaker: mapping  $S$  from  $M$  to  $F$
  - hearer: mapping  $R$  from  $F$  to  $M$
- **Average utility:** (identical for both players)

$$u(S, R) = \sum_m p_m \times \text{sim}(m, R(S(m)))$$

*vulgo: average similarity between speaker's meaning and hearer's meaning*

## Similarity function

- similarity is inversely related to distance
- requirements:

$$\forall x : \text{sim}(x, x) = 1$$

$$\forall x, y : \text{sim}(x, y) > 0$$

$$\forall x, y, z : \|x - y\| > \|x - z\| \rightarrow \text{sim}(x, y) < \text{sim}(x, z)$$

$$\forall x, y, z, w : \|x - y\| = \|z - w\| \rightarrow \text{sim}(x, y) = \text{sim}(z, w)$$

- suppose  $R$  is given and known to the speaker: which speaker strategy would be the best response to it?
  - every form  $f$  has a “prototypical” interpretation:  $R(f)$
  - for every meaning  $m$ :  $S$ 's best choice is to choose the  $f$  that minimizes the distance between  $m$  and  $R(f)$
  - optimal  $S$  thus induces a (quasi-) **partition** of the meaning space
  - Voronoi tessellation, induced by the range of  $R$

Okabe et al. (1992) prove the following lemma (quoted from Gärdenfors 2000):

## Lemma

*The Voronoi tessellation based on a Euclidean metric always results in a partitioning of the space into convex regions.*

## Definition

A set  $E$  of symmetric Nash equilibria is an *evolutionarily stable set* (ESSet) if, for all  $x^* \in E$ ,  $u(x^*, y) > u(y, y)$  whenever  $u(y, x^*) = u(x^*, x^*)$  and  $y \notin E$ . (Cressman 2003)

## Observation

*If  $R$  is a pure receiver strategy, the inverse image of any  $S \in BR(R)$  is consistent with the Voronoi tessellation of the meaning space that is induced by the image of  $R$ .*

## Theorem

*If a symmetric strategy is an element of some ESSet, the inverse image of its sender strategy is consistent with the Voronoi tessellation that is induced by the image of its receiver strategy.*

*sketch of proof:*

- game in question is symmetrized asymmetric game
- ESSets of symmetrized games coincide with SESets of asymmetric game (Cressman, 2003)
- SESets are sets of NE
- SESets are finite unions of Cartesian products of faces of the state space
- hence every component of an element of an SESet is a best reply to some pure strategy

## asymptotic stability

- in symmetrized games, a set  $E$  is an *asymptotically stable set of rest points* if and only if it is an ESSet
- in partnership games, at least one ESSet exists
- intuitive interpretation: under replicator dynamics + small effect of drift, system will eventually converge into some ESSet

- two-dimensional circular meaning space
- discrete approximation
- uniform distribution over meanings
- initial strategies are randomized
- update rule according to (discrete time version of) replicator dynamics

# The color space

- physical color space is of infinite dimensionality
- psychological color space has only three dimensions:
  - 1 brightness
  - 2 hue
  - 3 saturation

- languages differ wildly in how they carve up the color space into categories
- experimental investigation of color categorization using Munsell array

- for instance: English vs. Berinmo (Papua New Guinea)

- Berlin and Kay (1969): study of the typology of color words
- subjects with typologically distant native languages
- subjects were asked about prototype and extension of the basic color words of their native language
- English: 11 basic colors

# Berlin and Kay's study

# Implicational hierarchies

# A toy example

- suppose
  - circular two-dimensional meaning space
  - four meanings are highly frequent
  - all other meanings are negligibly rare
- let's call the frequent meanings  
Red, Green, Blue and Yellow

$$p_i(\text{Red}) > p_i(\text{Green}) > p_i(\text{Blue}) > p_i(\text{Yellow})$$

# A toy example

- suppose
  - circular two-dimensional meaning space
  - four meanings are highly frequent
  - all other meanings are negligibly rare
- let's call the frequent meanings  
Red, Green, Blue and Yellow

$$p_i(\text{Red}) > p_i(\text{Green}) > p_i(\text{Blue}) > p_i(\text{Yellow})$$

*Yes, I made this up without empirical justification.*

# Two forms

- suppose there are just two forms
- only one Strict Nash equilibrium (up to permutation of the forms)
- induces the partition  $\{\mathbf{Red}, \mathbf{Blue}\} / \{\mathbf{Yellow}, \mathbf{Green}\}$

# Three forms

- if there are three forms
- two Strict Nash equilibria (up to permutation of the forms)
- partitions  $\{\text{Red}\}/\{\text{Yellow}\}/\{\text{Green, Blue}\}$  and  $\{\text{Green}\}/\{\text{Blue}\}/\{\text{Red, Yellow}\}$
- only the former is **stochastically stable** (resistent against random noise)

# Four forms

- if there are four forms
- one Strict Nash equilibrium (up to permutation of the forms)
- partitions  
 $\{\text{Red}\}/\{\text{Yellow}\}/\{\text{Green}\}/\{\text{Blue}\}$

## Krifka's observations

- measure terms are vague
- some measure terms are ambiguous between different degrees of vagueness
- usually only simple expressions are ambiguous in this way
- complexifying an expression may reduce ambiguity

## vagueness

95 m: between 94.5 and 95.5 m

## ambiguity

- *The water has a temperature of  $40^\circ$ :  
 $38^\circ < T < 42^\circ$*
- *His body temperature is  $40^\circ$ :  
 $39.95^\circ < T < 40.05^\circ$*

## simple and complex expression

*His body temperature is  $39^\circ$ :  
cannot mean  $37^\circ < T < 41^\circ$*

## complexification

*The water has a temperature of  
exactly  $40^\circ$ :  $39.9^\circ < T < 40.1^\circ$*

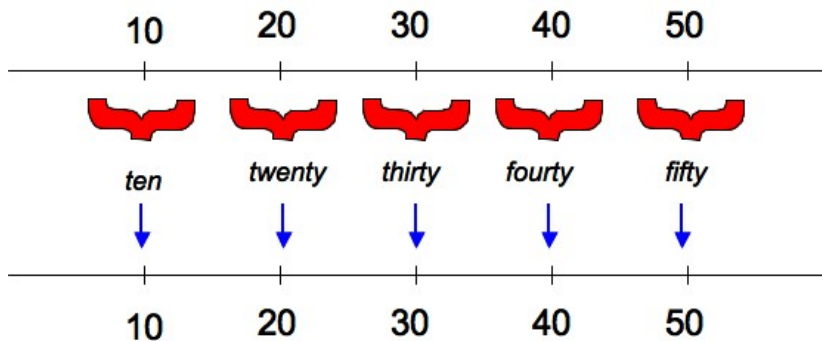

- Suppose the game setup is as before, with arithmetic difference as distance function

## ESS

- Sender:
  - meaning space is partitioned into continuous intervals of equal length
  - each interval is correlated with one signal
- Receiver:
  - each signal is mapped to the center of the corresponding interval

# General considerations

- suppose signals incur a cost for both sender and receiver
- modified utility function

$$u(S, R) = \sum_m p_m \exp(-(m - R(S(m)))^2) - c(S(m))$$

- intuitive idea:

$$c(\text{thirty-nine}) > c(\text{forty})$$

etc.

## ESSets

- general pattern as before
- additional constraint: in an ESS  $(S, R)$ , we have

$$\forall m : S(m) = \arg_f \max[\exp(-(m - R(f))^2) - c(f)]$$

- simultaneous
  - minimizing distance between  $m$  and  $R(S(m))$
  - minimizing costs  $c(S(m))$
- in equilibrium (ESSet), distance between  $m$  and  $R(S(m))$  need not be minimal

## Assessment

- this setup
  - predicts the possibility of vague interpretation: **good**
  - fails to predict the ambiguity between precise and vague interpretations (or different degrees of vagueness): **bad**

# Variable standard of precision

## Proposal

- required degree of precision depends on context
- modeling as Bayesian game with different utility function
- both players still have same utility function and know that function

$$u(S, R) = \sum_{m, \sigma} p_{m, \sigma} \exp(-(m - R(S(m)))^2 / \sigma^2) - c(S(m))$$

- high value of  $\sigma$ : precision doesn't matter very much
- low value of  $\sigma$ : precision is more important than economy of expression

# An example

- Suppose:
  - just two meanings: 39, 40
  - just two forms: *thirty-nine*, *forty*

$$c(\textit{thirty-nine}) - c(\textit{forty}) = \mathbf{c} > 0$$

- two standards of precision,  $\sigma_1$  and  $\sigma_2$

$$\begin{aligned}\sigma_1 &< \sigma_2 \\ \exp(-1^2/\sigma_1^2) &= d_1 \\ \exp(-1^2/\sigma_2^2) &= d_2 \\ 1 - d_1 &> \mathbf{c} \\ 1 - d_2 &< \mathbf{c} \\ \forall m, \sigma : p_{m, \sigma} &= .25\end{aligned}$$

# An example

## Intuitive characterization

- two standards of precision
- utility loss under vague interpretation is  $1 - d_i$
- utility loss due to usage of more complex expression is  $c$
- under  $\sigma_1$  precision is more important
- under  $\sigma_2$  economy of expression is more important
- uniform probability distribution over states

## meanings/signals

	$S$		$R$
	39	<i>thirty-nine</i>	39
	40	<i>forty</i>	40

## strategies

- $S_1/R_1$  : 
- $S_2/R_2$  : 
- $S_3/R_3$  : 
- $S_4/R_4$  : 

# Extensive form

# Utility matrices

$\sigma_1$

				
	$1 - \frac{c}{2}$	$d_1 - \frac{c}{2}$	$\frac{1+d_1-c}{2}$	$\frac{1+d_1-c}{2}$
	$d_1 - \frac{c}{2}$	$1 - \frac{c}{2}$	$\frac{1+d_1-c}{2}$	$\frac{1+d_1-c}{2}$
	$\frac{1+d_1}{2}$	$\frac{1+d_1}{2}$	$\frac{1+d_1}{2}$	$\frac{1+d_1}{2}$
	$\frac{1+d_1}{2} - c$	$\frac{1+d_1}{2} - c$	$\frac{1+d_1}{2} - c$	$\frac{1+d_1}{2} - c$
	$\frac{1+d_1}{2} - c$	$\frac{1+d_1}{2} - c$	$\frac{1+d_1}{2} - c$	$\frac{1+d_1}{2} - c$

$\sigma_2$

				
	$1 - \frac{c}{2}$	$d_2 - \frac{c}{2}$	$\frac{1+d_2-c}{2}$	$\frac{1+d_2-c}{2}$
	$d_2 - \frac{c}{2}$	$1 - \frac{c}{2}$	$\frac{1+d_2-c}{2}$	$\frac{1+d_2-c}{2}$
	$\frac{1+d_2}{2}$	$\frac{1+d_2}{2}$	$\frac{1+d_2}{2}$	$\frac{1+d_2}{2}$
	$\frac{1+d_2}{2} - c$	$\frac{1+d_2}{2} - c$	$\frac{1+d_2}{2} - c$	$\frac{1+d_2}{2} - c$
	$\frac{1+d_2}{2} - c$	$\frac{1+d_2}{2} - c$	$\frac{1+d_2}{2} - c$	$\frac{1+d_2}{2} - c$

## Evolutionary stability

- first subgame ( $\sigma_1$ ; precision is important): two ESS
  - $S_1/R_1$
  - $S_2/R_2$
- in either case, both expressions have a precise meaning and are interpreted exactly as intended
- second subgame ( $\sigma_2$ ; economy of expression is important): one ESSet
  - consists of  $S_3$  and all mixed strategies of  $R$
- Bayesian game:
  - two ESSets
  - any combination of ESSets of the two sub-games

## Assessment

- this setup
- predicts that
  - all number words receive a precise interpretation if precision is important
  - only short number words are used and receive a vague interpretation if economy is important
- **good**
- with larger dictionary prediction that there is no correlation between the interpretation of words between the different subgames
- for instance:
  - *forty* could mean 40 for  $\sigma_1$  and  $\{28...32\}$  for  $\sigma_2$
- **bad**

## Modified information sets

- idea
  - $S$  knows  $\sigma$ , but
  - $R$  doesn't
- then  $R$ 's interpretation of a word cannot depend on  $\sigma$

## Strategy space

- Sender strategies:
  - functions from pairs  $(m, \sigma)$  to signals
  - in the example:  $4 \times 4 = 16$  strategies, as before
- Receiver's strategies
  - functions from signals to meanings
  - in the example: only four such functions (as in the first version of the example)

# Extensive form

old game:

# Extensive form

new game:

## ESS

- resulting game has only two ESSs
  - ESS 1:
    - S: 
    - R: 
  - ESS 2:
    - S: 
    - R: 
- in either case
  - R always assumes precise interpretation
  - S always chooses correct word if  $\sigma$  is low
  - S always chooses short word if  $\sigma$  is high

## Open questions

- notion of ESS/ESSet only make sense for finite strategy space
- can results be maintained if meaning space is really continuous?
- S's signal gives information about value of  $\sigma$
- perhaps R's guess about value of  $\sigma$  should enter the utility function
- would explain why
  - it can be rational for S to use excessively complex phrases like *exactly forty* and short phrases like *forty* synonymously
  - *exactly forty* can only be interpreted precisely, while *forty* is ambiguous
